

Incident report analysis

Instructions

As you continue through this course, you may use this template to record your findings after completing an activity or to take notes on what you've learned about a specific tool or concept. You can also use this chart as a way to practice applying the NIST framework to different situations you encounter.

Summary	The organization experienced a Denial of Service (DoS) attack caused by a flood of incoming ICMP packets. The attacker exploited an unconfigured firewall, causing network services to become unavailable for two hours. The incident response team blocked malicious ICMP traffic, restored critical services, and investigated the attack. To strengthen network security, the organization implemented ICMP rate limiting, source IP address verification, network monitoring software, and an IDS/IPS system.
Identify	A malicious actor or actors targeted the company with an ICMP flood attack. The entire internal network was affected. All critical network resources needed to be secured and restored.
Protect	The organization strengthened its defenses by implementing a firewall rule to limit the rate of incoming ICMP packets, reducing the impact of ICMP flood attacks. Source IP address verification was also enabled on the firewall to detect and block spoofed IP addresses used by attackers.
Detect	Network monitoring software was deployed to continuously monitor network traffic and detect abnormal traffic patterns. An IDS/IPS system was also implemented to identify and filter suspicious ICMP traffic, allowing potential attacks to be detected more quickly.

Respond	During the incident, the response team blocked incoming ICMP packets, shut down non-critical network services, and restored critical services. After the investigation, the team updated firewall rules and deployed additional security controls to improve future incident response.
Recover	Critical network services were successfully restored after the attack was contained. The newly implemented firewall rules, source IP verification, network monitoring software, and IDS/IPS system help improve network resilience and reduce the likelihood of future DoS attacks disrupting business operations.
